DEVICE TEST

1, Explain behaviour of hub device

Hub is a device to connect network devices. It is a broadcasting device. When three PC's connected with hub namely A, B & C. If A ^hshares data to B. Hub device broadcast the data to all the device connected with it. But only the device has destination mac can able to open the data. During this process some data goes loss.

2, Explain behaviour of switch device

Switch is a device helps to connect network devices. It can do broadcast and unicast in some certain condition. It has the mac table contains port number & source mac when three PC's connected with switch namely A, B & C. If A shares the data to B. Switch first record the port number and source mac. If the data's source mac available in the mac table it will do the unicast or else broadcast. The collection of port number & source mac is called Address learning.

3, Explain behaviour of router device

Router devices is used to bread down the broadcast points. It can do the unicast. Router has the routing table which contains the network id, prefix and interface name. If we wants to connect three separate departments each as 4 PC's separately. First connect the department PC's with switch and further connect the switch with router to form network. we have to do the ip config for router with the first IP (it is formely followed in many companies standard) & it is not mandatory to config first ip.
